**Date:** 23/3/2024

## Abstract

The aim of this experiment is to understand Register Addressing Mode, Register Indirect Addressing Mode, ARM's Autoindexing Pre-indexed Addressing Mode, ARM's Autoindexing Post-indexing Addressing Mode and Program Counter Relative (PC Relative) Addressing Mode. We'll practice all of this in the lab.

## 1.Theory

### 1.1.Literal Addressing Mode

The immediate or literal addressing mode is where a literal number appears as a parameter to an instruction, such as `mov eax, 128` where 128 would be the literal or immediate value [1] .

Figure 1: Literal Addressing Mode [4].

### 1.2.Register Indirect Addressing Mode

We use a processor register to hold a memory location's address wherever the operand has been placed. This addressing mode would allow the execution of a similar set of instructions for various different memory locations. It can be done if we increment the content of the register and, thereby, point to the new location every single time [2] .

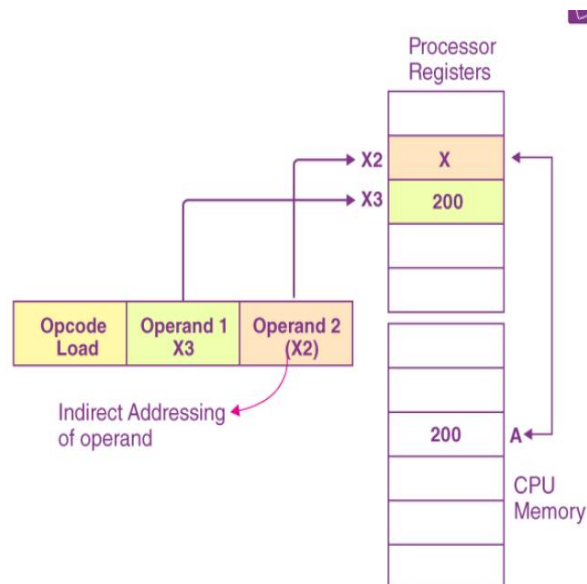

Figure 2 : Register Indirect Addressing Mode [2].

### 1.3.Register Indirect Addressing with an Offset

ARM supports a memory-addressing mode where the effective address of an operand is computed by adding the content of a register and a literal offset coded into load/store instruction [3].

#### 1.4.ARM's Autoindexing Pre-indexed Addressing Mode

This is used to facilitate the reading of sequential data in structures such as arrays, tables, and vectors. A pointer register is used to hold the base address. An offset can be added to achieve the effective address [4].

#### 1.5.ARM's Autoindexing Post-indexing Addressing Mode

This is similar to the above, but it first accesses the operand at the location pointed by the base register, then increments the base register [4].

#### 1.6.Program Counter Relative (PC Relative) Addressing Mode

Program counter relative addressing is a technique that allows you to access data or instructions relative to the current value of the program counter (PC) register. This can be useful for writing compact and portable code, as well as for implementing jump tables, switch statements, and loops [5].

#### 1.7.ARM's Load and Store Encoding Format

Memory access operations have a conditional execution field in bit 31, 03, 29, and 28. The load and store instructions can be conditionally executed depending on a condition specified in the instruction [4].

#### 1.8.Encoding Format of ARM's load and store instructions

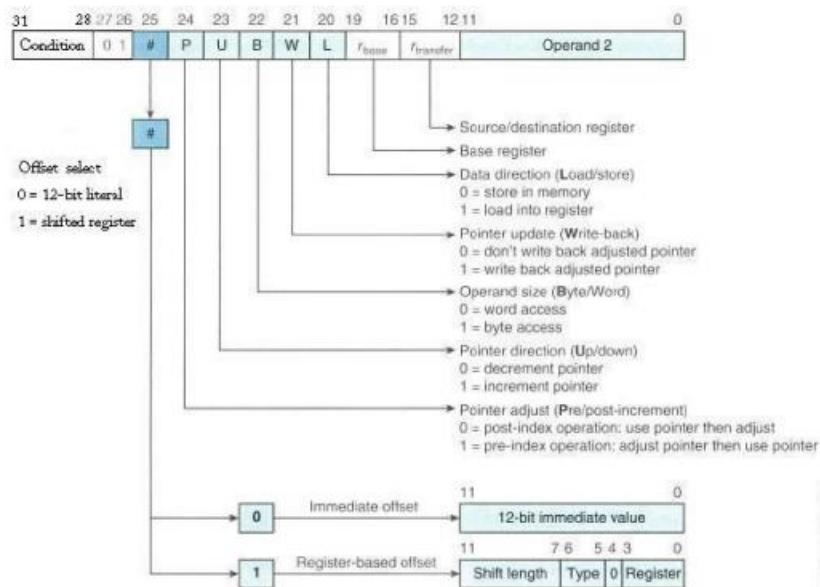

Figure 3 : Encoding Format of ARM's load and store instructions [4].

## 2.Procedure and Results

We practiced by running two examples and checking the results using debugging. Afterward, to ensure we understood the concept, we completed our lab assignment.

### 2.1 Example#1

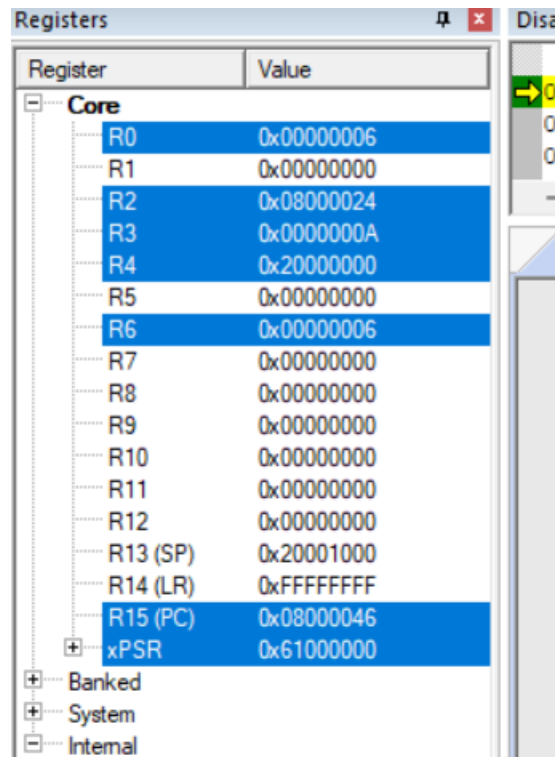

#### 2.1.1 Example#1 code

The code is to calculate the sum of numbers in array NUM1 and store sum in R0.

### 2.1.3 Result discussion

This code is written in ARM assembly language and is designed to calculate the sum of elements in an array. At the beginning, it sets up a stack pointer and a reset vector for handling system resets. In the data section, it declares variables including an array of numbers (NUM1) and a pointer to this array. In the code section, it defines a reset handler that initializes necessary registers and starts a loop to iterate through the array. Within the loop, it loads each element from the array, adds it to an accumulator, and decrements a counter until all elements are processed.

Finally, it stores the sum in memory and enters an infinite loop.

From the result the sum of array NUM1 is in R0 is 0x00000006.

## 2.2 Example#2

### 2.2.1 Example#2 code

The code is to count the length of the string and store the result in counter R1.

Figure 7: Example 2 result

### 2.2.3 Result discussion

This ARM assembly code initializes a string "Hello world!" in memory and then calculates its length. The reset handler sets up the initial environment. The main functionality begins with loading the address of the string into register R0 and initializing a counter for the string's length in register R1. It enters a loop where it loads each character of the string using byte-wise loading, updating the address pointer, and incrementing the counter until it encounters a null terminator, indicating the end of the string.

The result above show that the length of string "Hello World" is 0x0000000C.

## 2.3 LabWork1

### 2.3.1. LabWork1 code

The code add up all the numbers that are greater than 5 in the number array NUM1 and store the answer in R0.

```

Figure 8: labwork1 code

### 2.3.2. LabWork1 result

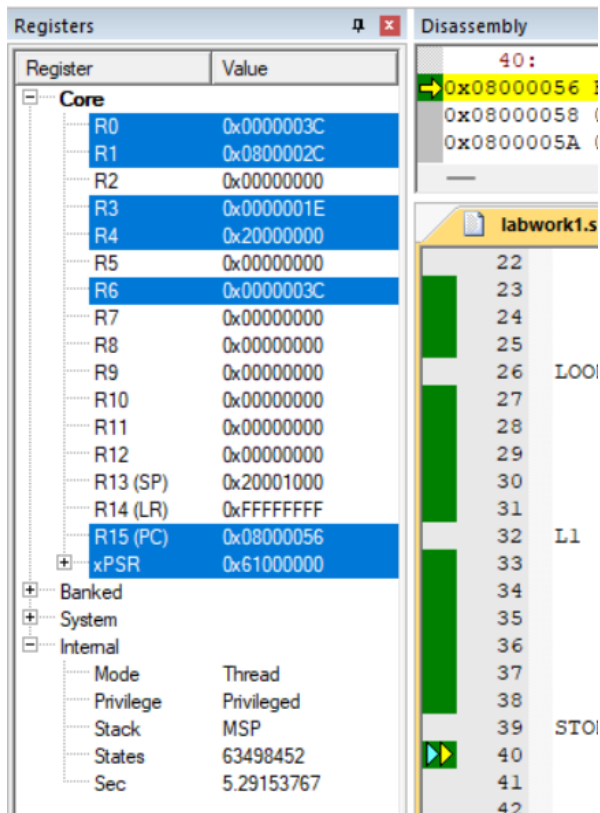

Figure 9 : labwork1 result

### 2.3.3. Result discussion

This ARM assembly code initializes an array of integers, **NUM1**, and calculates the sum of all elements in the array except for those that are greater than 5. It begins by loading the base address of the array into register R1 and the number of elements in the array into register R2. The accumulator register R0 is initialized to zero. Then, it enters a loop where it loads each element of the array and checks if it's greater than 5. If it's greater, it skips adding it to the accumulator. Otherwise, it adds it to the accumulator. After processing all elements, it stores the sum in memory. From the result R0 is 0x0000003C.

## 2.4 LabWork2

### 2.4.1 LabWork2 code

### 2.4.3 Result discussion

This ARM assembly code aims to find the maximum and minimum values in an array of integers. It initializes variables to store the maximum and minimum values, as well as their pointers, and the number of elements in the array. Within the main routine, it loads necessary pointers and initializes registers. It then iterates through the array, examining each element. For each element, it checks if it's negative, updates the maximum or minimum accordingly, and moves to the next element. It utilizes conditional branching and bitwise operations to handle negative numbers appropriately.

From the result Min is 0xFFFFFFFF and Max is 0x00000042.

### 2.5 Todo

The above code is to determine if the first string is a substring from the second string.

Figure 12: Todo code

### 3.Conclusion

In this experiment, we practiced using different types of ARM Addressing Modes that help us make decisions in our programs. We learned each of these types Register Addressing Mode, Register Indirect Addressing Mode, ARM's Autoindexing Pre-indexed Addressing Mode, ARM's Autoindexing Post-indexing Addressing Mode, Program Counter Relative (PC Relative) Addressing Mode. Finally, we used our knowledge to solve the tasks.
